

In pregnant rats administered topiramate (0, 20, 100, and 500 mg/kg/day or 0, 0.2, 2.5, 30, and 400 mg/kg/day) during the period of organogenesis, the frequency of fetal malformations (ectrodactyly, micromelia, and anelia) was increased in fetuses at 400 and 500 mg/kg/day. Embryotoxicity (reduced fetal body weights, increased incidences of structural variations) was observed at doses as low as 20 mg/kg/day. Clinical signs of maternal toxicity were seen at 100 mg/kg/day and above, and maternal body weight gain was reduced at doses of 100 mg/kg/day or greater. The no-effect dose (2.5 mg/kg/day) for embryofetal developmental toxicity in rats is less than the MRHD for epilepsy or migraine on a mg/m² basis.

In pregnant rabbits administered topiramate (0, 20, 60, and 180 mg/kg/day or 0, 10, 35, and 120 mg/kg/day) during the period of organogenesis, the frequency of fetal malformations (ectrodactyly, micromelia, and anelia) was increased in fetuses at 60 and 180 mg/kg/day. Embryotoxicity (reduced fetal body weights, increased incidences of structural variations) was observed at doses as low as 20 mg/kg/day. Clinical signs of maternal toxicity were seen at 100 mg/kg/day and above, and maternal body weight gain was reduced at doses of 100 mg/kg/day or greater. The no-effect dose (2.5 mg/kg/day) for embryofetal developmental toxicity in rabbits is less than the MRHD for epilepsy or migraine on a mg/m² basis.

8.2 Lactation Risk Summary
Topiramate is excreted in human milk. [See Data]. The effects of topiramate on milk production are unknown. Diarrhea and somnolence have been reported in breastfed infants whose mothers receive topiramate. The developmental and health benefits of breastfeeding should be considered along with the mother's clinical need for topiramate tablets and any potential adverse effects on the breastfed infant from topiramate tablets or from the underlying maternal condition.

8.3 Females and Males of Reproductive Potential
Contraception: Childbearing potential: If you are not planning a pregnancy you should use effective contraception because of the risks of oral clefts and SGA. [See Drug Interactions (7.4) and Use in Specific Populations (8.1)].

8.4 Pediatric Use
Adjunctive Treatment for Partial-Onset Epilepsy in Pediatric Patients 12 to 17 Years of Age: Safety and effectiveness in patients below the age of 2 years have not been established for the adjunctive treatment of partial-onset seizures, primary generalized tonic-clonic seizures, or seizures associated with Lennox-Gastaut syndrome. In a single randomized, double-blind, placebo-controlled investigation trial, the efficacy, safety, and tolerability of topiramate oral liquid and sprinkle formulations as adjunct to concurrent antiepileptic drug therapy in pediatric patients 12 to 24 months of age with refractory partial-onset seizures were assessed. After 20 days of double-blind treatment, topiramate (at fixed doses of 15, 15, and 25 mg/kg/day) did not demonstrate efficacy compared with placebo in controlling seizures.

In general, the adverse reaction profile for topiramate in this population was similar to that of older patients. Topiramate also produced a dose-related increase in the percentage of patients who had a shift from normal at baseline to high/very high above the normal reference range in total eosinophil count at end of treatment. The incidence of these abnormal shifts was 6% for placebo, 10% for 5 mg/kg/day, 9% for 15 mg/kg/day, 14% for 25 mg/kg/day, and 11% for topiramate dose. There was a mean decrease in eosinophil count in placebo-treated patients (5%) and 0 placebo-treated patients.

Topiramate resulted in an increased incidence of patients with increased creatinine (any topiramate dose 5%, placebo 0%), BUN (any topiramate dose 3%, placebo 0%), and protein (any topiramate dose 34%, placebo 8%), and an increased incidence of decreased potassium (any topiramate dose 7%, placebo 3%). This increased frequency of abnormal values was not dose-related. Creatinine was the only analyte showing a noteworthy increased incidence (topiramate 25 mg/kg/day 5%, placebo 0%) of a markedly abnormal increase. The significance of these findings is uncertain.

Topiramate treatment also produced a dose-related increase in the percentage of patients who had a shift from normal at baseline to high/very high above the normal reference range in total eosinophil count at end of treatment. The incidence of these abnormal shifts was 6% for placebo, 10% for 5 mg/kg/day, 9% for 15 mg/kg/day, 14% for 25 mg/kg/day, and 11% for topiramate dose. There was a mean decrease in eosinophil count in placebo-treated patients (5%) and 0 placebo-treated patients.

Topiramate produced a dose-related increase in hyperemesis in patients. [See Warnings and Precautions (5.10)].

Treatment with topiramate for up to 1 year was associated with reductions in SZORES for length, weight, and head circumference. [See Warnings and Precautions (5.10), Adverse Reactions (6)].

8.5 Geriatric Use
Safety and effectiveness in patients below the age of 2 years have not been established for the monotherapy treatment of epilepsy. [See Clinical Studies (14.1)].

8.6 Renal Impairment
The clearance of topiramate is reduced in patients with moderate (creatinine clearance 30 to 69 mL/min/1.73 m²) and severe (creatinine clearance <30 mL/min/1.73 m²) renal impairment. A dosage adjustment is recommended in patients with moderate or severe renal impairment. [See Dosage and Administration (2.5), Clinical Pharmacology (12.3)].

8.7 Patients Undergoing Hemodialysis
Topiramate is cleared by hemodialysis at a rate that is 4 to 6 times greater than in a normal individual. A dosage adjustment may be required. [See Dosage and Administration (2.6), Clinical Pharmacology (12.3)].

8.8 Overdosage
Signs and symptoms of overdose have been reported. Signs and symptoms include confusion, drowsiness, speech disturbance, blurred vision, diplopia, impaired mentation, lethargy, abnormal coordination, stupor, hypotension, abdominal pain, agitation, dizziness and depression. The clinical consequences were not observed in most cases, but death has been reported in patients who received overdoses of topiramate. Topiramate overdose has resulted in severe metabolic acidosis. [See Warnings and Precautions (5.4)].

A patient who ingested a dose of topiramate between 96 and 110 g was admitted to a hospital with a coma lasting 20 to 24 hours followed by full recovery after 3 to 4 days.

In the event of overdose, topiramate should be discontinued and general supportive treatment given until the patient is fully recovered. Hemodialysis is an effective means of removing topiramate from the body.

11 DESCRIPTION
Topiramate is a sulfamate-substituted monosaccharide. Topiramate tablets, USP are available as 25, 50, 100, and 200 mg tablets. Topiramate oral liquid is available as a white crystalline powder with a bitter taste. Topiramate is most soluble in alkaline solutions containing sodium hydroxide or sodium phosphate and having a pH of 9 to 10. It is freely soluble in acetone, chloroform, dimethylsulfoxide, and ethanol. The solubility in water is 9.8 mg/mL. Its saturated solution has a pH of 3.3. Topiramate is a white to off-white powder. The 50 mg strength also contains polyorbital, iron oxide yellow and iron oxide red. The 100 mg strength also contains polyorbital, iron oxide yellow and iron oxide red. The 100 mg strength also contains polyorbital and iron oxide red. The 200 mg strength also contains iron oxide red.

12 CLINICAL PHARMACOLOGY
12.1 Mechanism of Action
The precise mechanisms by which topiramate exerts its anticonvulsant and preventive migraine effects are unknown; however, preclinical data support four properties that may be important: (1) inhibition of voltage-gated calcium entry for epilepsy and the preventive treatment of migraine. Electrophysiological and biochemical evidence suggests that topiramate, at pharmacologically relevant concentrations, blocks voltage-dependent sodium currents, augments the activity of the neurotransmitter gamma-aminobutyric acid (GABA) at its receptor, antagonizes the AMPA/kainate subtypes of the glutamate receptor, and inhibits the carbonic anhydrase enzyme, particularly isozymes I and IV.

12.2 Pharmacodynamics
Topiramate has anticonvulsant activity in rat and mouse maximal electroshock seizure (MES) tests. Topiramate is only weakly effective in blocking tonic seizures induced by the GABA_A receptor antagonist, pentylenetetrazole. Topiramate is also effective in rodent models of epilepsy, which include tonic and absence-like seizures in the spontaneous epileptic rat (SEER) and tonic clonic seizure-induced in rats by kindling of the amygdala or by globus pallidus.

Changes (increases and decreases) from baseline in vital signs and systemic blood pressure: SBP, diastolic blood pressure (DBP), pulse rate occurred more frequently in pediatric patients (6 to 17 years) treated with various daily doses of topiramate (50, 100, mg, 200, 2, 3 mg/kg) than in patients treated with placebo in controlled trials for the preventive treatment of migraine. The most notable changes were SBP <90 mm Hg, DBP <50 mm Hg, SBP or DBP increases or decreases >20 mm Hg, and pulse increases or decreases >30 beats per minute. These changes were often dose-related, and were more frequently associated with the greatest treatment difference at the 200 mg dose level. Systematic collection of orthostatic vital signs has not been conducted. The clinical significance of these various changes in vital signs is not clearly established.

12.3 Pharmacokinetics
The oral bioavailability is bioequivalent to the immediate-release tablet formulation and, therefore, may be substituted as a therapeutic equivalent.

Absorption of topiramate is rapid, with peak plasma concentrations occurring at approximately 2 hours following a 400 mg oral dose. The relative bioavailability of topiramate from the tablet formulation is about 80% compared to a solution. The bioavailability of topiramate is not affected by food.

The pharmacokinetics of topiramate are linear with dose proportional increases in plasma concentration over the dose range 140 to 200 mg/day. The mean plasma elimination half-life is 21 hours after oral administration. Steady state is reached in about 4 days in patients with normal renal function. Topiramate is 15% to 41% bound to human plasma proteins with the blood concentration range of 0.5 to 250 mg/mL. The fraction bound decreased as blood concentration increased.

Carbamazepine and phenytoin do not alter the binding of topiramate. Sodium valproate, at 500 mg/mL, in concentration 10 times higher than considered therapeutic for valproate, decreased the protein binding of topiramate from 23% to 13%. Topiramate does not influence the binding of sodium valproate.

Metabolism and Excretion
Topiramate is not extensively metabolized and is primarily eliminated unchanged in the urine (approximately 60% of an administered dose). Six metabolites have been identified in humans, none of which constitutes more than 1% of an administered dose. The metabolites are formed via hydroxylation, hydrolysis, and glucuronidation. There is evidence of renal tubular reabsorption of topiramate. In rats, given probenecid to inhibit tubular reabsorption, along with topiramate, a significant increase in renal clearance of topiramate was observed. This interaction has not been evaluated in humans. Overall, oral plasma clearance (CL_R) is approximately 20 to 30 mL/min in adults following oral administration.

Renal Impairment
The clearance of topiramate was reduced by 42% in subjects with moderate renal impairment (creatinine clearance 30 to 69 mL/min/1.73 m²) and by 73% in subjects with severe renal impairment (creatinine clearance <30 mL/min/1.73 m²) compared to subjects with normal renal function (creatinine clearance >70 mL/min/1.73 m²). [See Dosage and Administration (2.4) and (2.5)].

Hemodialysis
Topiramate is cleared by hemodialysis. Using a high-efficiency, counterflow, single pass-dialyzer hemodialysis procedure, topiramate dialysis clearance was 120 mL/min with plasma flow through the dialyzer at 400 mL/min. This high clearance compared to 20 to 30 mL/min total oral clearance in healthy adults will remove a clinically significant amount of topiramate from the patient over the hemodialysis treatment period. [See Dosage and Administration (2.6), Use in Specific Populations (8.7)].

Hepatic Impairment
Plasma clearance of topiramate decreased a mean of 26% in patients with moderate to severe hepatic impairment.

Age, Gender, and Race
The pharmacokinetics of topiramate in elderly subjects (65 to 85 years of age, N=16) were evaluated in a controlled clinical study. The elderly subject population had reduced renal function (creatinine clearance <20%) compared to young adults. Following a single oral 100 mg dose, maximum plasma concentration for elderly and young adults was achieved at approximately 1 to 2 hours. Reflecting the primary renal elimination of topiramate, plasma clearance was reduced 21% and 19%, respectively, in elderly and young subjects, compared to young adults. Similarly, topiramate half-life was longer (13%) in the elderly. Reduced topiramate clearance resulted in slightly higher maximum plasma concentration (23%) and longer elimination half-life (19%) in elderly subjects. Topiramate clearance is decreased in patients with renal impairment to the extent that renal function is reduced. [See Dosage and Administration (2.4) and Use in Specific Populations (8.5)].

Clearance of topiramate in adults is not affected by gender or race.

Pediatric Pharmacokinetics
The effects of topiramate as an adjunctive treatment for adults with partial-onset seizures were established in six multicenter, randomized, double-blind, placebo-controlled trials (Studies 2, 3, 4, 5, 6, and 7), two comparing separate doses of topiramate and placebo and four comparing a single dosage with placebo, in patients with a history of partial-onset seizures, with or without secondarily generalized seizures. Patients in these studies were permitted a maximum of two antiepileptic drugs (AEDs) in addition to topiramate tablets or placebo. In each study, patients were stabilized on optimum dosages of their concomitant AEDs during baseline phase lasting between 4 and 12 weeks. Patients who experienced a pre-specified maximum number of partial-onset seizures, with or without secondarily generalized, during the baseline phase (12 seizures for 12-week baseline, 8 for 8-week baseline or 5 for 4-week baseline) were randomly assigned to placebo or a specified dose of topiramate tablets in addition to their other AEDs.

Following randomization, patients began the double-blind phase of treatment. In five of the six studies, patients received active drug beginning at 100 mg/day; the dose was then increased by 100 mg or 200 mg increments every other week until the assigned dose was reached, unless intolerance prevented increases. In the sixth study (Study 7), the 25 or 50 mg/day initial doses of topiramate were followed by respective weekly increments of 25 or 50 mg/day until the target dose of 200 mg/day was reached. After 4 weeks of treatment, patients entered a 8- to 12-week stabilization period. The numbers of patients randomized to each dose and the mean and median doses in the stabilization period are shown in Table 11.

Pediatric Patients 2 to 9 Years of Age
The effectiveness of topiramate as an adjunctive treatment for pediatric patients 2 to 9 years of age with partial-onset seizures was established in a multicenter, randomized, double-blind, placebo-controlled trial (Study 8), comparing topiramate and placebo in patients with a history of partial-onset seizures, with or without secondarily generalized seizures. [See Table 12].

Pediatric Patients 12 to 17 Years of Age
The effectiveness of topiramate for the preventive treatment of migraine in pediatric patients 12 to 17 years of age was established in a multicenter, randomized, double-blind, parallel-group trial (Study 13). The study enrolled 103 patients (40 male, 63 female) 12 to 17 years of age with episodic migraine headaches with or without aura. Patient selection was based on IHS criteria for migraines (using revised versions of the 1988 IHS pediatric migraine criteria) and was based on the presence of at least two migraine attacks per month for one week, and then the daily dosage was increased by 25 mg increments each week until reaching the assigned target dose or maximum tolerated dose (administered twice daily). Approximately 80% or more patients in each treatment group completed the study. The median average daily dosages were 45 and 79 mg/day in the target dose groups of topiramate 50 and 100 mg/day, respectively. Effectiveness of treatment was assessed by comparing each topiramate treatment group to placebo (ITT population) for the percent reduction from baseline to the last 12 weeks of the double-blind phase in the monthly migraine attack rate (primary endpoint). The percent reduction from baseline to the last 12 weeks of the double-blind phase in average monthly migraine attack rate is shown in Table 13. The 100 mg topiramate dose produced a statistically significant treatment difference relative to placebo of 28% reduction from baseline in the monthly migraine attack rate.

12.4 Antiepileptic Drugs
Potential interactions between topiramate and standard AEDs were assessed in controlled clinical pharmacokinetic studies in patients with epilepsy. The effects of these interactions on mean plasma AUC are summarized in Table 10.

Table 10. Summary of AED Interactions with Topiramate

AED Co-administered	AED Concentration	Topiramate Concentration
Phenytoin	NC or 25% increase	48% decrease
Carbamazepine (CBZ)	NC or 25% increase	40% decrease
CBZ epoxide ^a	NC	NC
Valproic acid	11% decrease	14% decrease
Phenobarbital	NC	NC
Primidone	NC	NE
Lamotrigine	4% at TPC doses up to 400 mg/day	13% decrease

^a = Plasma concentration increased 25% in some patients, generally those on a twice a day dosing regimen of 150 mg in patients, generally those on a twice a day dosing regimen of 150 mg in patients. [See Dosage and Administration (2.4)].

Table 11: Topiramate Dose Summary During the Stabilization Periods of Each of Six Double-Blind, Placebo-Controlled, Adjunctive Trials in Adults with Partial-Onset Seizures^a

Study	Stabilization Dose	Placebo ^b	Target-Topiramate Dosage (mg/day)
1	N	42	400 600 800 1,000

therapy used for temporary or emergency purposes was discontinued prior to randomization, in the double-blind phase, 470 patients were randomized to titrate up to 50 mg/day or 400 mg/day. If the target dose could not be achieved, patients were maintained on the maximum tolerated dose. Fifty-eight percent of patients achieved the maximum dose of 400 mg/day for 2 weeks, and patients who did not tolerate 150 mg/day were discontinued.

The primary efficacy assessment was a between-group comparison of time to first seizure during the double-blind phase. Comparison of the Kaplan-Meier survival curves of time to first seizure favored the topiramate 400 mg/day group over the topiramate 50 mg/day group (Figure 1). The treatment effects with respect to time to first seizure were consistent across various patient subgroups defined by age, sex, geographic region, baseline body weight, baseline seizure type, time since diagnosis, and baseline AED use.

Figure 2: Reduction in 4-Week Migraine Headache Frequency (Studies 11 and 12 for Adults and Adolescents)

Pediatric Patients 2 to 9 Years of Age
The conclusion that topiramate is effective as initial monotherapy in pediatric patients 2 to 9 years of age with partial-onset or primary generalized tonic-clonic seizures was based on a pharmacokinetic bridging approach using data from the controlled epilepsy trials described in labeling. This approach consisted of first showing a simple exposure-response relationship between pediatric patients down to 2 years of age and adults when topiramate was given as adjunctive therapy. Similarity of exposure-response was also demonstrated in pediatric patients 6 to less than 16 years of age and adults
